## ECE 101 Exploring Electrical Engineering

## - Circuits 1

- Electric Charge
- Voltage
- Current
- Resistance
- Power

## Electric Charge

- Particles can be neutral or charged
- Particle's electric charge ( $q$ or $Q$ ) affects its motion in the presence of changes in electric potential (aka electric field)
- Charge can be positive or negative.
- SI unit for charge: coulomb ( $1 \mathrm{C}=1 \mathrm{~A} \cdot \mathrm{~s}$ )
- Charge of a single electron is $\approx 1.602 \times 10^{-19} \mathrm{C}$.

## Voltage

- If there is a difference in electric potential between two spatial points, then a non-zero electric field will exist between them.
- This potential difference causes charged particles to move.
- The voltage $V$ is the amount of work done in moving a charge.
- SI unit for voltage: volt (V) ( $1 \mathrm{~V}=1 \mathrm{~J} / \mathrm{C}$ )
- Voltage represents external energy supplied to circuit

## Current

- Electric current $I$ is the rate at which charge flows through a cross-sectional area $A$.

$$
\text { Average: } I_{\text {ave }}=\frac{\Delta q}{\Delta t} \quad \text { Instantaneous: } I=\frac{d q}{d t}
$$

$\square$ Charge carriers: electrons (-), ions \& holes (+)
$\square$ Direct current (DC) $\rightarrow$ Carriers move in one direction only.
$\square$ Alternating current (AC) $\rightarrow$ Carrier direction varies periodically with time.
$\square$ In circuit analysis, conventional current is assumed, even if electrons are the primary charge carriers.

- SI unit for current: ampere (A) ( $1 \mathrm{~A}=1 \mathrm{C} / \mathrm{s}$ )

Positive charge moving:
From $V_{\text {high }}$ to $V_{\text {low }}$
$\rightarrow$ Energy is dissipated

From $V_{\text {low }}$ to $V_{\text {high }}$
$\rightarrow$ Battery supplies energy

Negative charge moving:
From $V_{\text {low }}$ to $V_{\text {high }}$
$\rightarrow$ Energy is dissipated

From $V_{\text {high }}$ to $V_{\text {low }}$
$\rightarrow$ Battery supplies energy

## Resistance

- The resistance $R$ is a measure of the opposition to direct current through a material.
- Interactions of charge carriers with the structure of the material impedes the current.
- Classes of materials:
$\square$ Conductor (low $R$ : e.g., ??)
$\square$ Insulator (high $R$ : e.g., ??)
$\square$ Semiconductor (intermediate $R$, e.g. ??)
- SI unit for resistance: ohm ( $\Omega$ )

## Ohm's Law

- Current $I$ through some materials is directly proportional to the potential difference $\Delta V$ between its ends.
$I \propto \Delta V$
- The resistance $R$ is defined as: $\quad R=\frac{\Delta V}{I}$
- The general form of Ohm's Law is:
$\Delta V=I R$

$$
R=\frac{\Delta V}{I}
$$

$$
I=\frac{\Delta V}{R}
$$

## Example:

$$
\begin{gathered}
\stackrel{I}{V_{1}} \stackrel{\xrightarrow{I}=2 \Omega}{V_{2}} \\
I=\frac{\Delta V}{R}=\frac{V_{1}-V_{2}}{R}
\end{gathered}
$$

| $V_{1}$ | $V_{2}$ | $I$ |  |
| :---: | :---: | :---: | :---: |
| 5 V | 0 V | 2.5 A |  |
| 5 V | 2 V | 1.5 A |  |
| 2 V | 5 V | -1.5 A |  |
| 1 V | -3 V | 2 A | If the potential difference <br> $\Delta V$ is zero, no current flows <br> through the resistor. |
| 3 V | 3 V | 0 A |  |

## Note:

It is understood that Ohm's Law refers to a potential difference. The $\Delta$ is usually omitted.

$$
V=I R \quad R=\frac{V}{I} \quad I=\frac{V}{R}
$$

Application of Ohm's Law
■ Given: Material of known resistance $R$
Voltage $V$ is applied across the material
Result: Current $I=V / R$ will flow through it.
■ Given: Material of known resistance $R$ Known current $I$ flowing through it Result: Voltage $V=I \cdot R$ exists across the material (known as a "voltage drop").

- Given: Known voltage $V$ across the material Known current $I$ through the material Result: Resistance of the material is $R=V / I$.

## Power

- Power is the rate at which energy is generated or dissipated by an electrical element.

$$
P=V I=\frac{V^{2}}{R}=I^{2} R
$$

where

$$
\begin{aligned}
& V=\text { Voltage (V or J/C) } \\
& I=\text { Current (A or } \mathrm{C} / \mathrm{s} \text { ) } \\
& R=\text { Resistance }(\Omega)
\end{aligned}
$$

Important because:
Measures output of a circuit (sound, light, heat, ...) Physical component can handle only a certain amount of power

- SI unit for power: watt (W) (1 W = $1 \mathrm{~J} / \mathrm{s}$ )

## Example:

$\stackrel{y=0.25 \mathrm{~A}}{\longrightarrow}$
$V_{1} \xrightarrow{V_{2}}$
What is the voltage drop across the resistor?
$V_{\text {drop }}=I R=(0.25 \mathrm{~A})(4.0 \Omega)=1.0 \mathrm{~V}$

What is the power dissipated by the resistor?
$P=I^{2} R=(0.25 \mathrm{~A})^{2}(4.0 \Omega)=0.25 \mathrm{~W}$

## Example:

- Find I and $P$.

## Questions:

- We have $P=V^{2} / R$ and $I^{2} R$. If $R$ is increased, does $P$ increase or decrease?
- Which has higher resistance, a 60 W bulb or a 120 W bulb?
- Which has a thicker filament, a 60 W bulb or a 120 W bulb? Hint: Household power is supplied with a fixed voltage. The current varies depending on the "load", the resistance of whatever is connected to the source.
